

## Favipiravir

Revised: June 15, 2024.

CASRN: 259793-96-9

## Drug Levels and Effects

### Summary of Use during Lactation

Favipiravir is an antiviral drug that is not approved in the United States by the US Food and Drug Administration. Information from one patient indicates that milk levels are low with a peak level at about 2 hours. One infant has reportedly been breastfed by a mother receiving favipiravir and pumping her breasts after doses with no adverse effects reported in the infant. Favipiravir has caused liver enzyme abnormalities, gastrointestinal symptoms, and serum uric acid elevations.[1,2] If favipiravir is used in a nursing mother, these parameters should be monitored in the breastfed infant.

## Drug Levels

*Maternal Levels.* A lactating woman took a single 200 mg dose of favipiravir (Favimol, Neutec Pharmaceutical Company) and provided milk samples at 0.5, 2 and 4 hours after the dose. Milk concentrations were 0.3, 5.5 and 2.7 mg/L, respectively.[3]

*Infant Levels.* Relevant published information was not found as of the revision date.

## Effects in Breastfed Infants

A nursing mother with a positive PCR for COVID-19 was prescribed favipiravir with a loading dose of 1600 mg twice on the first day, then 600 mg every 12 hours from day 2 to day 5. She breastfed her 15-month-old COVID-19-negative infant just before each dose of the drug. She pumped and discarded her milk between doses. No symptoms were observed in the baby during drug use and no abnormalities were detected in the baby's hematological and biochemistry tests. The infant was followed for 6 months and was fed breastmilk and complementary feeding, did not develop any symptoms.[4]

## Effects on Lactation and Breastmilk

Relevant published information was not found as of the revision date.

## Alternate Drugs to Consider

Nirmatrelvir, Remdesevir
